Abstract:

Concise explanation of how a high performance HVAC system works in a high performance home.
Perhaps the most frequently raised concern from owners of high performance homes is:

**How can I be saving energy, money, and wear and tear on my equipment if it seems as though my system is running a lot more than systems in other homes?**

The neat thing about the answer to this question is that your high performance home is not only saving you energy, money, and equipment life; it’s also delivering more comfort, health, and safety to boot. And you cannot split the pieces of your system up—it’s an all-or-nothing performance package. Here is how and why it works for you:

**1.** When you build a **tight thermal envelope**, you get to build in a smaller HVAC system, whether it be your furnace, you’re A/C compressor, or your air handler (this is basically the fan motor that moves the heated or cooled air from the unit to the rest of your home). And a smaller system uses less energy than a larger system.

When your HVAC is sized correctly, it can be as much as **40% smaller** than the typically over-sized HVAC system. Smaller systems may run longer to achieve the same level of conditioning, but their total energy consumption is still lower. The equipment runs more efficiently and lasts longer if it is not short-cycling. Just like a car’s motor, it’s in start-up that most of the wear and tear occurs and it runs the least efficiently.

**2.** Your high performance home is equipped with an outside air intake duct and a fan cycling control that keeps track of how often your air handler has been running. The outside air and fan cycling control ensure that a measured amount of outside air is introduced into your home each hour and that all of the air in your home is thoroughly mixed every hour. This is key to controlling indoor pollutants and interior moisture levels, as well as keeping the temperatures even throughout all your rooms. Especially during mild weather, the FanCycler™ can make your air handler run more than air handlers in homes without active fresh air ventilation. And, since the FanCycler™ is pulling in outside air that may have to be heated or cooled, there can be additional energy associated with its use. On the other hand, during these same mild periods, the FanCycler™ may be pulling in outside air that **reduces** energy use because the outside air requires less conditioning (for example, pulling in cooler outside air at night that reduces air conditioning). For a typical 1,500 ft² home1, the annual energy cost for just the air handler’s operation due to the FanCycler™ is somewhere between $33 and $49, depending on your climate.

Your home’s overall performance—its energy costs, indoor air quality, thermal comfort, moisture control, combustion safety—is based on the HVAC system as a whole. Your builder and HVAC contractor have set up the system for optimal performance. Before you alter the fan cycling control settings, check with your builder or an HVAC contractor with experience in residential mechanical ventilation.2 You can’t take the “V” out of HVAC (V stands for ventilating in the Heating, Ventilating & Air Conditioning acronym). Unlike other homes, your high performance home has a dedicated and regimented system for introducing, filtering, and conditioning fresh air.

**3.** When your HVAC is sized correctly, it can be as much as **40% smaller** than the typically over-sized HVAC system. Smaller systems may run longer to achieve the same level of conditioning, but their total energy consumption is still lower. The equipment runs more efficiently and lasts longer if it is not short-cycling. Just like a car’s motor, it’s in start-up that most of the wear and tear occurs and it runs the least efficiently.

**4.** For the details of how these numbers were generated, see the report on the modeling study on the BSC website: [http://www.buildingscience.com/resources/mechanical/ventilation_centralfan.htm](http://www.buildingscience.com/resources/mechanical/ventilation_centralfan.htm). Your builder may have decided, or you may decide, that the initially higher building product 2.

1 For the details of how these numbers were generated, see the report on the modeling study on the BSC website: [http://www.buildingscience.com/resources/mechanical/ventilation_centralfan.htm](http://www.buildingscience.com/resources/mechanical/ventilation_centralfan.htm).

2 Your builder may have decided, or you may decide, that the initially higher building product emissions in your new home — from paints, cabinets, furnishings — justify fan cycling control settings that introduce more outside air for a “break-in” period. This will result in a small one-time energy penalty if the fan cycling settings are subsequently re-set for more long-term and regular control of indoor pollutants.
